- 2. Recurrent neural networks
  - 2.1 SRN
  - 2.2 LSTM
  - 2.3 Bi-LSTM
  - 2.4 GRU

# What is Deep Learning (DL)?

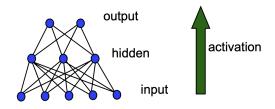

A machine learning subfield of learning representations of data. Exceptional effective at learning patterns.

Deep learning algorithms attempt to learn (multiple levels of) representation by using a hierarchy of multiple layers.

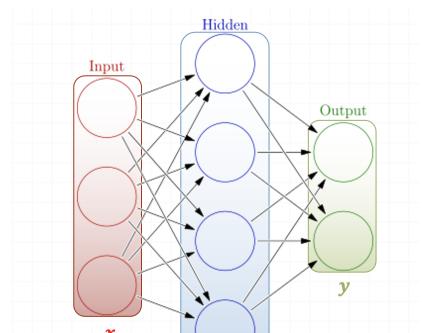

#### Feed-forward neural networks

➤ A typical multi-layer network consists of an input, hidden and output layer, each fully connected to the next, with activation feeding forward.

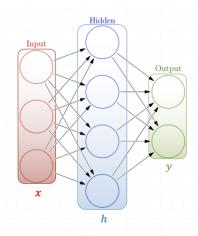

▶ The weights determine the function computed.

### Feed-forward neural networks

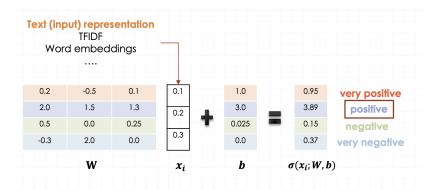

### Feed-forward neural networks

Weights 
$$h = \sigma(W_1x + b_1)$$
  $y = \sigma(W_2h + b_2)$  Activation functions

$$4 + 2 = 6$$
 neurons (not counting inputs)  
 $[3 \times 4] + [4 \times 2] = 20$  weights  
 $4 + 2 = 6$  biases  
26 learnable parameters

### One forward pass

### Training

https://medium.com/@ramrajchandradevan/the-evolution-of-gradient-descend-optimization-algorithm-4106a6702d39

Optimize objective/cost function  $J(\theta)$ 

Generate error signal that measures difference between predictions and target values

Use error signal to change the weights and get more accurate predictions

Subtracting a fraction of the gradient moves you towards the (local) minimum of the cost function

### Updating weights

objective/cost function  $J(\theta)$ 

Update each element of  $\theta$ :

$$\theta_j^{new} = \theta_j^{old} - \alpha \frac{d}{\theta_i^{old}} J(\theta)$$

Matrix notation for all parameters ( $\alpha$ : learning rate):

$$\theta_j^{new} = \theta_j^{old} - \alpha \nabla_{\theta} J(\theta)$$

Recursively apply chain rule though each node

### Notes on training

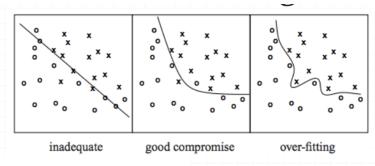

- Not guaranteed to converge to zero training error, may converge to local optima or oscillate indefinitely.
- ► However, in practice, does converge to low error for many large networks on real data.
- Many epochs (thousands) may be required, hours or days of training for large networks.
- ➤ To avoid local-minima problems, run several trials starting with different random weights (*random restarts*).
  - ► Take results of trial with lowest training set error.
  - Build a committee of results from multiple trials (possibly weighting votes by training set accuracy).

### Hidden unit representations

- Trained hidden units can be seen as newly constructed features that make the target concept linearly separable in the transformed space.
- On many real domains, hidden units can be interpreted as representing meaningful features such as vowel detectors or edge detectors, etc..
- However, the hidden layer can also become a distributed representation of the input in which each individual unit is not easily interpretable as a meaningful feature.

## Overfitting

Learned hypothesis may fit the training data very well, even outliers (noise) but fail to generalize to new examples (test data)

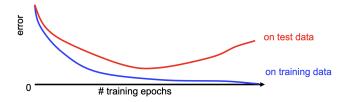

http://wiki.bethanycrane.com/overfitting-of-data

### Overfitting prevention

Running too many epochs can result in over-fitting.

- Keep a hold-out validation set and test accuracy on it after every epoch. Stop training when additional epochs actually increase validation error.
- ▶ To avoid losing training data for validation:
  - Use internal K-fold CV on the training set to compute the average number of epochs that maximizes generalization accuracy.
  - Train final network on complete training set for this many epochs.

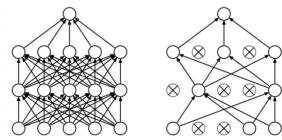

### Regularization

Dropout

Randomly drop units (along with their connections) during training

Each unit retained with fixed probability p, independent of other units

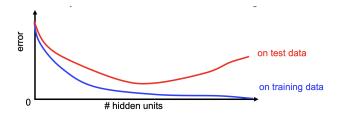

Hyper-parameter p to be chosen (tuned)

Srivastava, Nitish, et al. "Dropout: a simple way to prevent neural networks from overfitting." Journal of machine learning research (2014)

### Determining the best number of hidden units

- ► Too few hidden units prevents the network from adequately fitting the data.
- Too many hidden units can result in over-fitting.

- Use internal cross-validation to empirically determine an optimal number of hidden units.
- Hyperparameter tuning

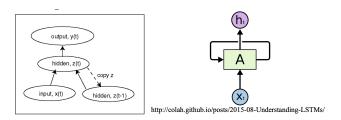

# Recurrent Neural Networks

# Recurrent Neural Network (RNN)

- ► Add feedback loops where some units' current outputs determine some future network inputs.
- RNNs can model dynamic finite-state machines, beyond the static combinatorial circuits modeled by feed-forward networks.

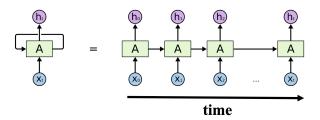

# Simple Recurrent Network (SRN)

- Initially developed by Jeff Elman ("Finding structure in time," 1990).
- Additional input to hidden layer is the state of the hidden layer in the previous time step.

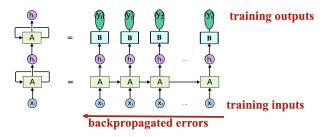

### **Unrolled RNN**

▶ Behavior of RNN is perhaps best viewed by "unrolling" the network over time.

## Training RNNs

- RNNs can be trained using "backpropagation through time."
- Can viewed as applying normal backprop to the unrolled network.

# Vanishing gradient problem

Suppose we had the following scenario:

Day 1: Lift Weights

Day 2: Swimming

Day 3: At this point, our model must decide whether we should take a rest day or yoga. Unfortunately, it only has access to the previous day. In other words, it knows we swam yesterday but it doesn't know whether had taken a break the day before.

Therefore, it can end up predicting yoga.

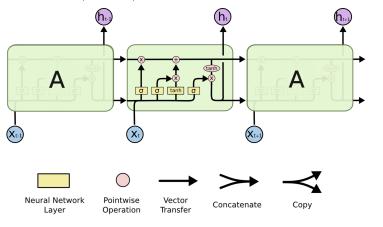

- Backpropagated errors multiply at each layer, resulting in exponential decay (if derivative is small) or growth (if derivative is large).
- Makes it very difficult train deep networks, or simple recurrent networks over many time steps.
- LSTMs were invented, to get around this problem.

https://towardsdatascience.com/

## Long Short Term Memory

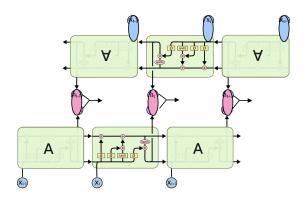

- ► LSTM networks, add additional gating units in each memory cell.
  - Forget gate
  - Input gate
  - Output gate
- Prevents vanishing/exploding gradient problem and allows network to retain state information over longer periods of time.

# LSTM network architecture | https://colah.github.io/posts/2015-08-Understanding-LSTMs/

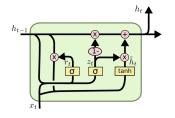

# Bi-directional LSTM (Bi-LSTM)

Separate LSTMs process sequence forward and backward and hidden layers at each time step are concatenated to form the cell output.

# Gated Recurrent Unit (GRU)

- ► Alternative RNN to LSTM that uses fewer gates (Cho, et al., 2014)
  - ► Combines forget and input gates into "update" gate.
  - Eliminates cell state vector

$$z_{t} = \sigma(W_{z} \cdot [h_{t-1}, x_{t}])$$

$$r_{t} = \sigma(W_{r} \cdot [h_{t-1}, x_{t}])$$

$$\tilde{h}_{t} = tanh(W \cdot [r_{t} * h_{t-1}, x_{t}])$$

$$h_{t} = (1 - z_{t}) * h_{t-1} + z_{t} * \tilde{h}_{t}$$

#### Attention

- ► For many applications, it helps to add "attention" to RNNs.
- Allows network to learn to attend to different parts of the input at different time steps, shifting its attention to focus on different aspects during its processing.
- Used in image captioning to focus on different parts of an image when generating different parts of the output sentence.
- ▶ In MT, allows focusing attention on different parts of the source sentence when generating different parts of the translation.

# Summary

### Summary

- ▶ Deep learning can be applied for automatic feature engineering
- Recurrent neural networks are are ideal for sequential data such as text

### Practical 6
